Design of an Online Cab Booking System

The AV-CABS plans to build a database for managing the information about cab bookings by a customer and provide a user-friendly interface. A customer books a ride online and the request is forwarded to the driver so the ride can be booked. The system aims to make booking cabs easy and convenient for customers.

When the user signs up, his/her name and mobile number are stored in the database.

Driver's name, Mobile number, and Car details are also present in the database.

FUNCTIONALITIES

The application's functional requirements include a good design and a friendly interface.

- At first the user does the login/signup process if not already logged in.
- User sets the pickup location and drop location.
- The fare is calculated based on the distance and demand.
- The user selects the ride and payment options.
- The application then connects the user to the nearest and most suitable driver.
- After the driver accepts the ride request and completes the ride, the user is given the option for rating/review.

We will use google maps embedding for the locations.

Our Database will have certain constraints like :

- No user can have the same Mobile numbers.
- Users can have the same names.
- A Driver can not be assigned to another customer if he's completing a ride.

When the user signs up, his/her name and mobile number are stored in the database.

Driver's name, Mobile number, and Car details are also present in the database.

- Once the ride is booked, the user can see the location of the driver and the driver details like his mobile number, car details etc. (user can access the driver details from the database when the ride is booked)
- Once the driver accepts the ride, he can access the details of the user from the database like his/her phone number, name, location etc.
- The company can access the details from the database at all times.
